ACKNOWLEDGMENTS

This report was prepared for the Economic Services and Health and Recovery Services Administrations of the Department of Social and Health Services. Funding was provided by the Health and Recovery Services Administration.

Sincere thanks go to program staff who thoughtfully reviewed this report, including Nancy Anderson, M.D., M.P.H., June Hershey, Mo Lally, Mo Considine, Casey Zimmer, BJ Bailey, and Aurea Figueroa. The First Steps Work Group also provided helpful comments.

Thanks go to Elizabeth Kohlenberg, Ph.D., Director of Research and Data Analysis, DSHS, and Fred Fiedler, Ph.D., Acting RDA Director, for oversight and overall project management.

Nora Ellsworth provided her expertise and assistance with printing and report production.

Jason Fry, Greg Kirkpatrick, and Francina Reynolds have our sincere appreciation for maintaining the RDA computer network, a system that meets the diverse demands of the agency's managers, researchers, analysts, programmers, and talented support staff.

The First Steps Database would not exist without the contributions of the Center for Health Statistics, Department of Health, which provides birth certificate files, and the Health and Recovery Services Administration, DSHS, which provides Medicaid claims data. Special thanks to Karen Lathrop and Phyllis Reed at the Center for Health Statistics for providing us with state and county abortion data for various years.

CSO Profiles:

Birth and Unintended Pregnancy Statistics For Community Services Offices, 1991-2002

EXECUTIVE SUMMARY

Many diverse communities comprise Washington State. The communities described in this report represent the neighborhoods surrounding the Department of Social and Health Services Community Services Offices (CSOs). This study portrays characteristics of the female population residing within the CSO boundaries and subgroups of the total population. The measures reported pertain most directly to women in their typical child-bearing years, from age 15 to age 44.

Medicaid coverage of births. Pregnant women with family incomes at or below 185% of the Federal Poverty Level are eligible for medical insurance coverage through Medicaid in Washington. The proportion of births funded by Medicaid directly reflects the economic well-being of the CSO community at a given point in time. In 2001-02, 43.4% of all Washington births were covered by Medicaid. The proportion of births with Medicaid funding ranged from 15.8% in King East CSO (King County) to 80.2% in Toppenish-Wapato CSO (Yakima County).

Non-citizens are eligible for Medicaid coverage for pregnancy and delivery. The proportion of births to non-citizens has increased from 3.1% in 1991-92 to 8.0% in 2001-02. This represents a nearly three-fold increase. Five CSOs demonstrated a ten-fold or greater increase in the proportion of births to non-citizens.

Unintended pregnancy. An unintended pregnancy is a pregnancy which a woman states was either mistimed (wanted later) or unwanted at the time of conception. In 2001-02, for Washington State overall, 40.2% of all births were unintended at the time of conception. The unintended pregnancy rate ranged from an estimated 31% in King East CSO (King County) to an estimated 53.2% in Republic Outstation (Ferry County).

Number and Rates of Births. The numbers and rates of births are reported for five two-year time periods, from 1991-92 to 2001-02 and for two subgroups of women: (1) women who lived in mostly low-income areas, with at least 27% of the population at or below 185% of the FPL (referred to as low-income women) and (2) women who lived in mostly higher-income areas, with less than 27% of the population at or below 185% of the FPL (referred to as higher-income women).

The statewide birth rate for women 15-44 decreased by 9% from 66.4 per 1000 in 1991-92 to 60.5 per 1000 in 2001-02. The birth rate for young women, age 15-24, decreased by 24%, from 85.7 per 1000 in 1991-92 to 64.9 per 1000 in 2001-02. In 2001-02, birth rates for older women, 25-44, both low income and higher income, were essentially the same, at 58.7 and 58.4 per 1000. By 2001-02, the birth rate for young higher-income women (50 per 1000) was lower than that for older higher-income women (58.4 per 1000) while the birth rate for young low-income women (84.4 per 1000) remained higher than that for older low-income women (58.6 per 1000).

Birth Rates at the CSO Level. Birth rates for most CSOs are close to the statewide rate of 60.5 per 1000 in 2001-02. Five CSOs are distinguished by birth rates of greater than 90 per 1000. The five CSOs with the highest birth rates had three factors in common: very high rates of poverty, low educational attainment, and a high proportion of births to Hispanic women. The five CSOs with the lowest birth rates demonstrated less poverty, high educational attainment, and a low proportion of births to Hispanic women. In the CSOs with the highest and lowest birth rates, the differences between birth rates for women who lived in mostly low-income areas and those who lived in mostly higher-income areas were small. This suggests that, at least in these ten CSOs, the community where people reside, its values, and beliefs, may be a greater influence on birth rates than income *per se*.

CONCLUSIONS. The findings emphasize the importance of considering community values and cultural differences in family planning activities. The communities and subgroups of Washington State have diverse values and beliefs. Family planning information and education need to be available to all women so that every woman is able to make informed decisions based on her personal values.

CSO Profiles:
Birth and Unintended Pregnancy
Statistics for Community Services Offices, 1991-2002

SUMMARY OF FINDINGS

Many diverse communities comprise Washington State. The communities described in this report represent the neighborhoods surrounding the Department of Social and Health Services (DSHS) Community Services Offices (CSOs). DSHS Economic Services Administration (ESA) assigns clients to CSOs based on the ZIP code of the client's residence. CSOs described here reflect those providing service as of August 15, 2005, including full-service CSOs, branch offices, and outstations. CSO boundaries are not fixed, they are not established by law or administrative rule, and they change over time. Changes in policies or demographics may result in changes in the populations served at each CSO, and CSOs may merge into one office or be split into two or more CSOs.

The measures presented here portray characteristics of the female population residing within the CSO boundaries and subgroups of the total population. The measures pertain most directly to women in their typical child-bearing years, from age 15 to age 44.

MEDICAID COVERAGE OF BIRTHS

One important characteristic of CSO communities is the proportion of Medicaid-eligible pregnant women. Pregnant women with family incomes at or below 185% of the Federal Poverty Level (FPL) are eligible for medical insurance coverage through Medicaid in Washington.

- **In 2001-02, 43.4% of all Washington births were covered by Medicaid.**
- **Toppenish-Wapato CSO, in Yakima County, with 80.2% of births covered by Medicaid, was the CSO with the highest Medicaid rate.** The proportion of births with Medicaid funding in Toppenish-Wapato was **nearly double** the state rate.
- **King East CSO, in King County, with 15.8% of births covered by Medicaid, was the CSO with the lowest Medicaid rate.** The proportion of births with Medicaid funding in King East was **less than half** the state rate.

The proportion of births funded by Medicaid directly reflects the economic well-being of the CSO community at a given point in time. Program changes may also influence trends in this proportion over time. For example, a major change in Medicaid eligibility for pregnant women in Washington occurred in 1989 when eligibility was expanded to 185% of the FPL. This was just one component of the First Steps program. The statewide increase in the proportion of Medicaid-funded births from 37.7% in 1991-92 to 42.1% in 1995-96 is explained by the increased use of services by First Steps' target population of low-income women.

Medicaid women were divided into three major groups: women receiving cash grants (TANF/AFDC), medical-only citizens, and medical-only non-citizens. (Medical-only women are

Medicaid-eligible solely because of pregnancy.) While variation in the proportions of grant women and medical-only citizens was generally consistent with the overall proportion of Medicaid births, the proportion of non-citizens increased significantly during the study period.

- **In 1991-92, 3.1% of all Washington births were to non-citizens. In 2001-02, the proportion increased to 8.0%.** This change represents a nearly three-fold increase.
- The CSOs with the highest proportions of births to non-citizens in 2001-02 were **Mattawa (56%), Pasco (33.4%), Othello (31.9%), and Sunnyside (31.7%).**
- A few CSOs demonstrated dramatic increases in the proportion of births to non-citizens over the study period. **The CSO with the greatest increase in births to non-citizens was Everett: from 0.2% in 1991-92 to 8.8% in 2001-02. This change represents a nearly forty-fold increase.** Other CSOs with large increases in the proportion of births to non-citizens included Federal Way, King South, Renton-Holgate, and Columbia River. The increase in the proportion of births to non-citizens was in the range of ten-fold at each of these CSOs.

UNINTENDED PREGNANCY

Low-income women have higher rates of unintended pregnancy than higher-income women. *Unintended pregnancy* is defined here as a pregnancy resulting in a live birth which a woman states was either mistimed (wanted later) or unwanted at the time of conception. The unintended pregnancy rates presented for CSOs (based on the Pregnancy Risk Assessment Monitoring System survey and adjusted for poverty within each CSO) parallel the proportion of Medicaid-funded births.

Unintended pregnancy rates for all births in Washington State have changed little since 1993, the first year this measure became available for women giving birth. While the rate of unintended pregnancy for all births has fluctuated between 39.5% and 40.2% between 1991-92 and 2001-02, the decreases in Washington birth and abortion rates, especially for young women, imply that many unintended pregnancies have actually been averted.

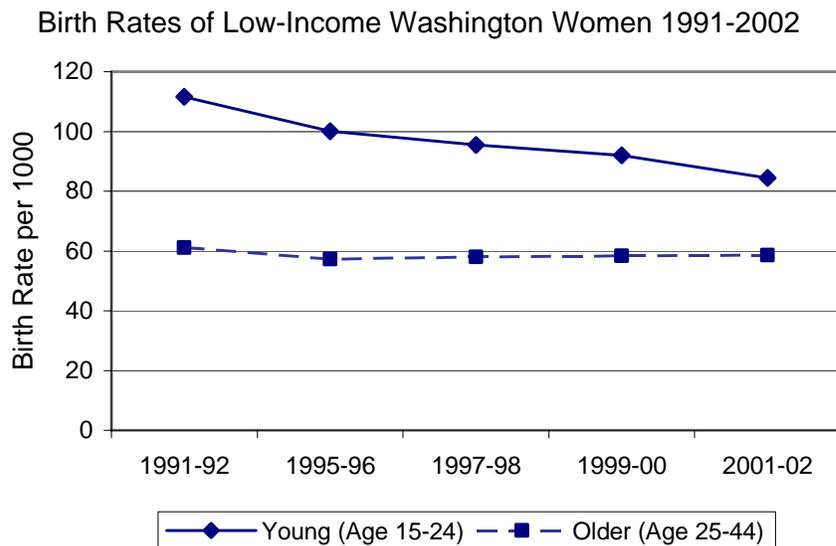

Low-income women, with unintended pregnancy rates of 66.2% for grant women (TANF/AFDC), 57.8% for medical-only citizens, and 38.4% for non-citizens in 2001-02, continue to demonstrate much higher rates than higher-income women. Higher-income (non-Medicaid) women had an unintended pregnancy rate of 26.8% in 2001-02.

- **In 2001-02, for Washington State overall, the rate of unintended pregnancy resulting in birth was 40.2%.**
- **Republic Outstation, with an estimated 53.2% unintended pregnancy rate, was the CSO with the highest rate.**
- **King East CSO, with an estimated 31% unintended pregnancy rate, was the CSO with the lowest rate.**

NUMBERS AND RATES OF BIRTHS

In this report, the birth rate was defined as the total number of live births to women in the specified age group divided by the number of women in that age group (times 1000). Birth rates are presented for the total population of women age 15-44 and for two subgroups of the total: (1) women who lived in low-income areas, with at least 27% of the population at or below 185% of the FPL (referred to as low-income women) and (2) women who lived in higher-income areas, with less than 27% of the population at or below 185% of the FPL (referred to as higher-income women).

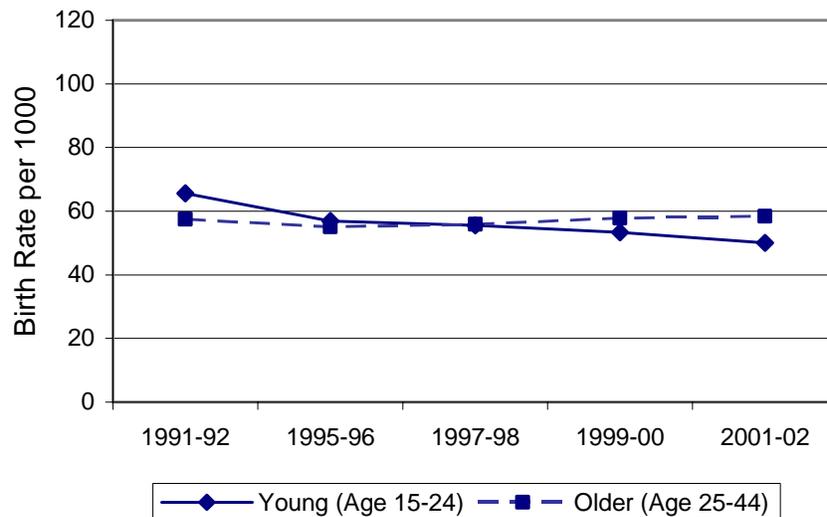

- **The overall birth rate for women 15-44 decreased by 9%**, from 66.4 per 1000 in 1991-92 to 60.5 per 1000 in 2001-02, while the number of births was essentially unchanged (79,021 in 1991-92 and 78,582 in 2001-02).
- **The birth rate for young women, age 15-24, decreased by 24%**, from 85.7 per 1000 in 1991-92 to 64.9 per 1000 in 2001-02. Birth rates for young women, both low income and higher income, showed similar decreases of 24%.
- The birth rate for older women, age 25-44, was stable during this time period, at 58.7 per 1000 in 1991-92 and 58.4 in 2001-02. **In 2001-02, birth rates for older women, both low income and higher income, were essentially the same, at 58.6 and 58.4 per 1000, respectively.**
- The yearly number of births to low-income women decreased slightly from 33,661 in 1991-92 to 32,352 in 2001-02.¹

¹ The number of births to low-income women is measured as the number of births that occurred in areas where at least 27% of the population was at or below 185% of the FPL. The actual count of Medicaid-paid births for the same time periods are similar: 29,791 (1991-92), 32,358 (1995-96), 32,683 (1997-98), 33,481 (1999-00), and 34,105 (2001-02). The increase (14%) in actual Medicaid-paid births compared to the decrease (4%) in the number of births to women in low-income areas may be related to increasing difficulty in obtaining private insurance.

- **The birth rate for low-income women decreased from 78.6 per 1000 in 1991-92 to 68.4 per 1000 in 2001-02. This represents a decrease of 13%.** The birth rate for young low-income women decreased 24% while the birth rate for older low-income women decreased 4%.
- For higher-income women, the number of births was essentially stable at 45,361 births per year in 1991-92 and 46,230 births per year in 2001-02.
- The birth rate for higher-income women decreased slightly from 59.5 per 1000 in 1991-92 to 56.0 per 1000 in 2001-02. This represents a decrease of 6%. The birth rate for young higher-income women decreased 24% while the birth rate for older higher-income women increased 2%.
- By 2001-02, the birth rate for young higher-income women (50.0 per 1000) was **lower** than the birth rate for older higher-income women (58.4 per 1000) while the birth rate for young low-income women (84.4 per 1000) remained **higher** than that for older low-income women (58.6 per 1000).

Birth Rates of Higher Income Washington Women 1991-2002

BIRTH RATES AT THE CSO LEVEL

Birth rates of the individual CSOs vary widely. While the difference between 2001-02 statewide birth rates for low-income (68.4 per 1000) and higher-income (56.0 per 1000) women is relatively small, much larger differences are seen at the CSO level.

- **Belltown CSO demonstrated the lowest birth rates for all women, low-income women, and higher-income women: 31.4, 25.7, and 34.0 per 1000, respectively, in 2001-02.**
- **Mattawa CSO demonstrated the highest birth rates for all women and low-income women (both 133.8 per 1000) in 2001-02, and Toppenish-Wapato CSO demonstrated the highest birth rates for higher-income women (141.9 per 1000).**

The following table shows the five CSOs with the lowest and highest birth rates:

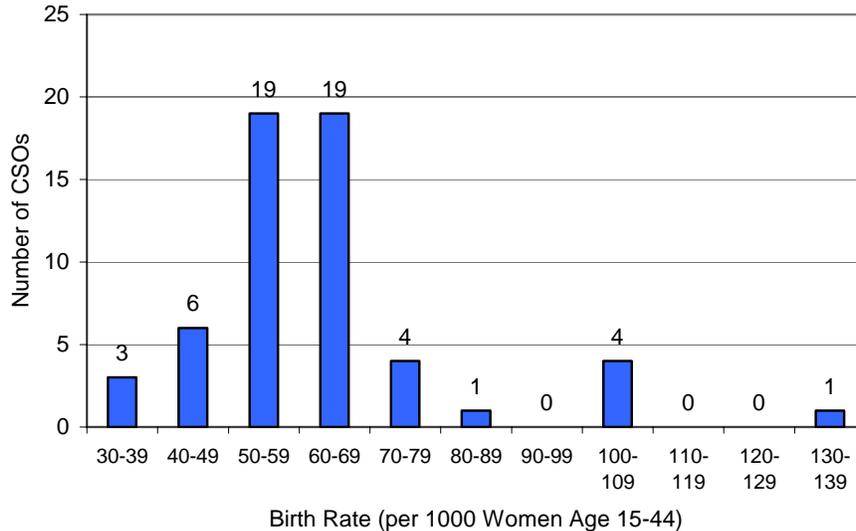

2001-02 Birth Rates per 1000 Women

	ALL WOMEN		LOW INCOME		HIGHER INCOME	
LOWEST	Belltown	31.4	Belltown	25.7	Belltown	34.0
	Colfax	33.5	Colfax	27.5	Capitol Hill	37.3
	Capitol Hill	36.7	King North	30.0	Cathlamet	38.7
	Ellensburg	41.7	Friday Harbor	33.3	Port Townsend	42.3
	King North	41.8	Capitol Hill	36.0	King North	46.3
	Statewide	60.5		68.4		56.0
	Sunnyside	101.1	Sunnyside	101.9	Othello	78.7
	Othello	103.3	Othello	107.1	Moses Lake	81.7
	Pasco	107.7	Toppenish-Wapato	107.9	Pasco	91.4
	Toppenish-Wapato	108.4	Pasco	115.0	Sunnyside	93.8
HIGHEST	Mattawa	133.8	Mattawa	133.8	Toppenish-Wapato	141.9

CSOs with the lowest birth rates include two university towns (Colfax, site of Washington State University, and Ellensburg, site of Central Washington University). Belltown, with 24% Medicaid births, and King North, with 21.5% Medicaid, represent two of the three CSOs with the lowest proportions of Medicaid births. These five CSOs demonstrated high educational attainment (just 6.5% of mothers were not high school graduates) and a low proportion of births to Hispanic women (8.0% Hispanic births) (2001-02 data).

Despite the wide range in birth rates, birth rates for most CSOs are close to the statewide rate of 60.5 per 1000 as shown in the figure below. Five CSOs are distinguished by total birth rates of greater than 90 per 1000, much greater than the statewide birth rate. These five CSOs with the highest birth rates have three factors in common: very high rates of poverty (75% Medicaid births), low educational attainment (49.4% of mothers were not high school graduates), and a high proportion of births to Hispanic women (71.8% Hispanic births) (2001-02 data).

Distribution of 2001-02 Birth Rates for Washington CSOs

In the United States, women of Hispanic descent have slightly higher birth rates overall, and, among Hispanic women in the U.S., women of Mexican descent have the highest birth rates: 116.6 per 1000 for Mexican women in 1997 (Ventura, Martin, Curtin, and Mathews, 1999). In Washington State, where 15.7% of all births occurred to women of Hispanic ethnicity in 2001-02, Mexican origin was associated with the vast majority (79.3%) of the Hispanic births. Thus, the high birth rates seen in Washington CSOs with a high proportion of Hispanic women are consistent with trends observed for the United States overall.

TRENDS IN BIRTH AND ABORTION RATES

The early 1990s marked a turning point in the increasing birth rates that young women in the United States had demonstrated through the 1980s. The U.S. birth rate for 15-19 year olds peaked in 1991 at 62.1 per 1000, and for 20-24 year olds the peak of 116.5 per 1000 occurred in 1990. Washington State has been a leader in this trend; only five other states showed greater declines in birth rates for 15-19 year olds from 1991 to 2002 (Martin et al., 2003).

The decreasing birth rates among teens nationwide are likely due to increased abstinence and increased use of condoms and other methods of contraception such as hormonal injections, implants, and other more effective methods of birth control among sexually active teens. Studies also suggest that the increased economic growth experienced in the United States in the 1990s had an impact on declining teen birth rates. Increased economic opportunities experienced by millions of Americans may have encouraged teenagers to invest in more education, to pursue better career opportunities, and to postpone parenthood (AECF, 2001; Ventura, Mathews and Hamilton, 2001; Darroch and Singh, 1999).

These decreases in U.S. birth rates have been greater for teens (15-19 years old) than for 20-24 year olds, and for younger teens (15-17 years old) compared to older teens (18-19 years old). The largest decreases have occurred among young African-American women and the smallest

decreases among young Hispanic women. In 2003, Hispanics had the highest teen birth rate, 82.2 per 1000 for 15-19 year olds, compared to 41.7 per 1000 for all 15-19 year olds (Ventura, Abma, Mosha, Henshaw, 2004).

Similar patterns have been demonstrated in Washington State. Birth rates for teens 15-17 years old reached their peak of 32.9 per 1000 in 1992, and by 2003, had decreased 53.5% to 15.3 per 1000. Birth rates for teens 18-19 years old reached their peak of 89.4 per 1000 in 1993, and by 2003, had declined 37.5% to 55.9 per 1000. Birth rates for 20-24 year olds are higher than for either group of teens and have decreased less over this time period (DOH, 2005).

The substantial decreases in teen birth rates contribute to the overall decrease of 24% for women 15-24 described in this report. Similarly, the 24% decrease in birth rates for women 15-24 contributes to the overall decrease of 8.7% for Washington birth rates. The change in birth rate for older women (25-44 years of age) was very small (0.3%). Among older women, the 4% decrease for low-income women was countered by an increase of 2% in the birth rate for higher-income women.

Two particularly encouraging trends were observed for Washington in 2001-02. The birth rate for young higher-income women dropped to a level (50.0 per 1000) lower than that for older higher-income women (58.4 per 1000). In addition, the birth rate for older low-income women (58.6 per 1000) was essentially the same as that for older higher-income women (58.4 per 1000).

These accomplishments were not shared by all CSOs. In 24 CSOs, the birth rates for older higher-income women were greater than or equal to those for younger women; however, in thirty CSOs, birth rates were higher for young higher-income women than for older women. (These comparisons are not possible for the three CSOs with no higher-income areas identified.) In just eight CSOs, the birth rates were lower for young low-income women than for older low-income women. On the other hand, birth rates for older low-income women were lower than those for older higher-income women in 29 CSOs.

Washington's decreasing abortion rates also closely parallel those at the national level. From 1990 to 2000, the rate of induced abortions for the U.S. decreased from 27.4 per 1000 to 21.3 per 1000, a decrease of 22.2%. In Washington, the abortion rate decreased by 19% from 24.1 per 1000 in 1991-92 to 19.6 per 1000 in 2001-02. The abortion rate decreased among all age groups except women 40-44 years old. The largest decreases from 1991-92 to 2001-02 were experienced by younger women. The abortion rate for teens 18-19 years olds decreased from 53.7 per 1000 in 1993 to 34 per 1000 in 2003. This represents a decrease of 37%. For teens 15-17 years old, the abortion rate decreased from 24.8 per 1000 in 1993 to 13.3 per 1000 in 2003. This represents a decrease of 46%.

The combined decreases in birth rates and abortion rates reflect dramatic decreases in pregnancy rates, both in the United States and in Washington State. Many different factors have contributed to these changes and the patterns of birth rates for Washington's CSOs. Statewide, income level is associated with higher birth rates among young women age 15-24. In the CSOs with the highest and lowest birth rates, the differences between birth rates for women who lived in mostly low-income areas and those who lived in mostly higher-income areas were small. This

suggests that, at least in these ten CSOs, the community where people reside, its values, and beliefs, may be a greater influence on birth rates than income *per se*.

These issues emphasize the importance of seriously considering community values and cultural differences in family planning activities. The communities and subgroups of Washington State have diverse values and beliefs. Family planning information and education need to be available to all women so that every woman is able to make informed decisions based on her personal values.

INTRODUCTION

Community Services Offices (CSOs) provide a variety of financial and other support services locally to persons and families in need. The staff in Washington's CSOs determines eligibility for cash, medical, and food assistance programs, such as Medicaid and Temporary Assistance for Needy Families (TANF), and they provide social services including case management.

The purpose of this report is to present data profiles for each of the 57 CSOs in Washington State, including full-service CSOs, branch offices, and outstations. The data include demographic and pregnancy-related indicators by CSO, using CSO catchment area boundaries as of August 15, 2005. Numbers and rates are reported for the estimated total population living within each CSO's 2005 boundaries. Numbers and rates are also reported separately for women who lived in mostly low-income areas and those who lived in mostly higher-income areas. Low-income areas were defined as having at least 27% of the population at or below 185% of the FPL. Higher-income areas were defined as having less than 27% of the population at or below 185% of the FPL.

Family planning is an essential component of health and wellness and is particularly important in programs designed to help low-income clients achieve and maintain self-sufficiency. In the early 1990s, Washington started a pilot program to bring family planning services into Department of Social and Health Services (DSHS) CSOs to increase access to these services for low-income clients. In 1994, family planning services were introduced into the remaining CSOs. Washington State requires that family planning assistance and information be made available to all TANF clients and potential clients (RCW 74.12.400 and 410). In 1997, when welfare reform was implemented, decreasing the number of unintended pregnancies among TANF clients received strong emphasis.

The DSHS Health and Recovery Services Administration (HRSA, formerly Medical Assistance Administration), in partnership with the Economic Services Administration (ESA) and individually contracted family planning agencies, manages Washington's CSO-based family planning program. The family planning team at each CSO includes, at a minimum, the Family Planning Nurse, Social Services Supervisor, Work First Supervisor, and CSO Administrator. In many CSOs, management from the contracted family planning agency, CSO front-line staff, Call Center Supervisor, Clerical Supervisor, and Employment Security Department all participate in developing the CSO's family planning program. Each CSO has a written plan that addresses referral systems, data sharing, communication methods, and the use of staff resources at the CSO.

CSO-based family planning is only one of a number of approaches implemented by HRSA to address unintended pregnancy among low-income women.

- All Medicaid-eligible pregnant women and new mothers receive counseling about achieving their desired family size and assistance with family planning services. Since July 2000, First Steps Maternity Support Services providers have been responsible for

discussing pregnancy planning with each client and determining if she has initiated a method during the postpartum period.

- Women who are Medicaid-eligible solely because of pregnancy receive extended Medicaid coverage limited to family planning services for a full year postpartum. Full-scope Medicaid coverage ends after the second month for these women.
- Women and men (who are U.S. citizens and are not otherwise Medicaid eligible) with incomes at or below 200% of the FPL are eligible for family planning services through Washington's family planning waiver program, known as TAKE CHARGE. TAKE CHARGE was implemented July 1, 2001.

All of these programs emphasize that the client's preferences, beliefs, and attitudes are essential to the process of selecting a family planning method in order for the method to be used successfully.

While these programs have the potential to reach as broad a target population as possible within existing policies, it is recognized that limiting the number of publicly-funded deliveries requires interventions at multiple levels, including:

- Increasing access to family planning services
- Educating communities about the benefits of avoiding unintended pregnancies
- Changing individual behavior.

In Washington State as of 2003, nearly 40% of all pregnancies resulting in live births were unintended at the time of conception. More than 60% of all births to women on cash assistance were unintended at the time of conception (Pregnancy Risk Assessment Monitoring System survey data, 2003).

The Washington Department of Health and the Department of Social and Health Services share a common objective of reducing unintended pregnancies in Washington State and are working together to impact these statistics. While CSOs have made great strides in contributing to the achievement of this goal, data tools like this report are needed to complement local knowledge and information in the assessment of the reproductive and family planning services needs of CSO clientele and implementation of community-based interventions.

METHODS

Data tables in this report are similar in format to the February 2000 *CSO Profiles* report published by the Department of Social and Health Services. This report differs from the 2000 *CSO Profiles* in the methods used to identify low-income women. In this report, each CSO was divided into areas where mostly low income persons lived, defined as having at least 27% of the population at or below 185% of the FPL, and areas where mostly high income persons lived, defined as having less than 27% of the population at or below 185% of the FPL. These distinctions were based on income data from the 2000 U.S. census.

Region-specific data for 2001-02 were added to individual CSO tables to permit comparisons between each CSO and the region in which it is located. Data are presented as average annual numbers and rates for two-year intervals, covering selected periods between 1991-92 and 2001-2002. While the format is similar to previous reports, the methodology is quite different. Therefore, one cannot assess changes in births, abortions and unintended pregnancy statistics by comparing data in the 2005 *CSO Profiles* report to past reports.

Various sources were used to compile data for the birth and abortion rates, unintended pregnancy rates and Medicaid statistics in the data tables. This section is organized by each item's order of appearance in the data tables.

DATA SOURCES

CSO-specific population estimates are based on data from the Washington State Department of Health (Washington State Population Estimates for Public Health, DOH, Vista Partnership, Krupski Consulting, October 2004) which reflect U.S. census data for 1990 and 2000, with estimates for the intervening years. CSO boundaries were defined by the Economic Services Administration. Population estimates at the census block level were aggregated to obtain the approximate numbers of persons at the CSO level.

The *First Steps Database* (FSDB) links vital statistics from birth and death certificates to information on Medicaid-paid maternity services and Medicaid eligibility files. The FSDB relies on data from the Department of Social and Health Services Health and Recovery Services Administration (HRSA) and the Department of Health Center for Health Statistics (DOH-CHS). All data on cash assistance eligibility and Medicaid eligibility were determined using the Office of Financial Management eligibility history file.

The *Pregnancy Risk Assessment and Monitoring System* (PRAMS) is an on-going, population-based surveillance system sponsored by the Centers for Disease Control and Prevention (CDC) and implemented in Washington by the state Department of Health (DOH). PRAMS survey data from 1993-2002 were linked to the FSDB to provide statewide and CSO-level estimates of the proportion of women with unintended pregnancies.

Abortion numbers and rates are based on data from the Washington State Center for Health Statistics *Pregnancy and Induced Abortion Statistics* publications for various years. Abortion rates are the number of abortions to women in each age category per 1000 women in that age

group. The number of abortions per CSO was estimated by applying the appropriate county abortion rates for women 15-24 and 25-44 to the estimated CSO population in those age groups.

METHODS

Appendix C provides additional technical information about the methods described below.

CSO Boundaries

The area surrounding each DSHS Community Services Office (CSO) is used in this report to define communities and neighborhoods within Washington State. ESA assigns clients to CSOs based on the ZIP code of the client's residence. CSOs described here reflect those providing service as of August 15, 2005, including full-service CSOs, branch offices, and outstations. CSO boundaries are not fixed, they are not established by law or administrative rule, and they change over time. Changes in policies or demographics may result in changes in the populations served at each CSO, and CSOs may merge into one office or be split into two or more CSOs. The CSOs reported here differ from those in the 2000 *CSO Profiles*.

CSO boundaries were developed by the GIS team of the Research and Data Analysis Division of the Department of Social and Health Services in collaboration with ESA staff. CSO, Outstation, and Branch locations (geocodes) were based on addresses provided by ESA (4/29/2005). CSO catchments were based on ZIP codes provided by ESA (4/11/2005 and updated 8/15/2005). CSO catchments follow Dynamap Zip Boundaries v2005a. ZIP codes unassigned by ESA (00072, 00073, 00074, and 00076) were allocated to the nearest CSO according to political or physical boundaries in order to simplify the CSO map. The same CSO boundaries were applied for all time periods in the study.

The methodology used to define CSO boundaries in this report is different from that used in previous CSO Profiles reports.

Population Estimates

Population estimates provide the basis for calculating changes in the context of population change. Small area population estimates are based on data from the Department of Health. Population estimates were linked geographically to the CSO level using census tract and block groups.

CSO population estimates are presented by the total population (all men, women and children) and the population of childbearing women (women ages 15 to 44). Data for women ages 15 to 24 and ages 25 to 44 are also presented.

Births with Medicaid-Paid Maternity Care

The percent of births with Medicaid-paid maternity care represents the proportion of total live births to women ages 15-44 that were identified in the First Steps Database as receiving Medicaid-paid maternity care. Low-income pregnant women that receive medical assistance

funded with a mix of state and federal monies are included in the numerator. Medicaid women were divided into three major groups: non-citizens, grant women (TANF/AFDC), and medical-only citizens. In addition to these major groups, a small number of Medicaid women are eligible through other Medicaid programs or received services with eligibility type unknown.

The percent of births to grant women (TANF/AFDC) is the proportion of live births to women 15-44 who receive cash grants through TANF (AFDC prior to July 1997). Grant women are eligible for full-scope medical coverage through Medicaid.

The percent of births to medical-only citizens is the proportion of live births to women 15-44 who have family income at or below 185% of the FPL, are Medicaid-eligible solely because of pregnancy, and are U.S. citizens (or qualified aliens with more than five years of U.S. residence).

The percent of births to non-citizens is the proportion of live births to women 15-44 who were non-citizens. Non-citizen women include those who are not legally admitted for permanent residence, lack temporary residence status, are not lawfully present in the U.S., or are lawful non-citizen permanent residents (referred to as qualified aliens) with less than five years of U.S. residence. Determination of non-citizen status is available only for the Medicaid population.

The percent of births to non-Medicaid women is the proportion of live births to women 15-44 who had no Medicaid-paid maternity care.

Unintended Pregnancy

One question in the annual PRAMS survey of women who gave birth asks how the woman felt about her pregnancy at the time of conception. Women who answered that at the time of conception they would have preferred to become pregnant at a later time or not at all are categorized as having a birth from an unintended pregnancy.

Due to the PRAMS sampling strategy and sample size, it is not possible to directly compute numbers of unintended pregnancies at the CSO level. Therefore, the statewide unintended pregnancy rate was adjusted for Medicaid status (TANF/AFDC, Medical Only Citizens, and Non-Citizens) at the CSO level.

Number and Rates of Births

Numbers of liveborn births by CSO boundary area were identified using geo-coded birth certificates from the Washington Department of Health, Center for Health Statistics. These were then linked to the First Steps Database.

The *birth rates* are calculated as the number of live births to women by specific age category, per 1000 women in the corresponding age group. Numbers of births and birth rates were calculated for three age groups: women ages 15-44, women ages 15-24 and women ages 25-44. Birth rates are suppressed when they are based on fewer than five births.

Numbers and Rates of Births by Income Level

These data provide basic comparisons of birth rates among low-income women and higher-income women residing in each CSO.

Low-income women are those who lived in low-income areas, defined as having at least 27% of residents with income less than 185% of the FPL. Higher-income women are those who lived in higher-income areas, defined as having fewer than 27% of residents with incomes less than 185% of the FPL. The variable used to define the ratio of income to the poverty level was individual income in 1999 (P88 from the SFS Summary Files of the 2000 U.S. Census). The FPL limit of 185% was selected to correspond to Medicaid eligibility for pregnant women in Washington. A preliminary break point of 25% was assigned by ArcMap Jenks natural breaks technique, which identifies break points by picking the class breaks that best group similar values and maximize the difference between classes. This was empirically adjusted to 27% to balance the higher-income and low-income areas within as many CSOs as possible.

The determination of higher-income and low-income areas was based on data from the 2000 U.S. Census. All the census block groups in Washington were divided into the two groups defined above: higher-income areas and low income areas. The CSO boundaries were overlaid on the census block groups to determine the population of low- and higher-income areas in each CSO. Geo-coded birth certificates were assigned to the appropriate income group and CSO. Similar methods were described by Krieger et al. (2002).

Birth rates were calculated as the total number of births for each age and income group within each CSO divided by the population estimate of the number of women of the appropriate age and income group for each CSO. Data are presented for women ages 15-44, 15-24 and 25-44.

No higher-income areas were identified in three CSOs (Mattawa, Newport Branch Office, and Goldendale Branch Office) so all births and residents of those CSOs were assigned to the low-income group.

Numbers and Rates of Abortions

Abortion data are reported anonymously to the Department of Health Center for Health Statistics (DOH-CHS). Reported data contain only general information, such as the woman's county of residence and age. Estimating CSO-specific abortion rates is thus less exact than methods for estimating birth rates, where geographic identifiers are available. All statistics in the DOH reports refer to induced abortions.

DOH-CHS publishes age-specific numbers of abortions by county of residence in *Pregnancy and Induced Abortion Statistics* publications. To estimate the number of abortions per CSO, county abortion rates for women in age groups 15-24 and 25-44 were applied to the estimated CSO population in those age groups. The county abortion rates used were based on the proportional distribution of births in the CSO. Abortion rates were calculated as the number of abortions per 1,000 women per age group. Appendix B lists the age-specific county abortion rates used in estimating the number of abortions at the CSO level. Estimated numbers and rates of abortions were not published when the number of events was less than five.

Limitations

CSOs represent small areas with boundaries that may change over time. Rates may randomly fluctuate from one year to another, particularly when the number of events is small. Reporting in two-year averages minimizes these potentially large variations. Rates were suppressed when the number of events was less than five. Reporting rates for very small CSOs, such as branch offices, is particularly problematic.

The 2005 CSOs (as of August 15, 2005) and their boundaries were used for all time periods and all data in order to provide appropriate comparisons over time. The character of a CSO community may change over time although the boundaries are constant. In particular, the distribution of higher-income and low-income areas was based on the 2000 U.S. Census. If the 1990 census had been used, the assignments might have been different. For example, the socioeconomic status (SES) of a CSO community may increase over time through gentrification, or the SES may decrease due to loss of a key industry. To some degree, the percent Medicaid for all births provides an independent indicator of SES for the CSO.

The presumed under-count of non-citizens in the U.S. Census may affect precision in birth rates. While the number of births to non-citizens is known with a high degree of precision, the number of non-citizen women may be under-represented. Some studies apply a correction factor of 15-20% to census-based estimates of the non-citizen population in the U.S. (Costanzo et al., 2001; Bean et al., 2001). Such corrections were not possible in this report. To the extent that the population of non-citizen women 15-44 years old is under-counted, birth rates may also be overstated.

Statewide estimates of unintended pregnancy are based on annual data collected by the Department of Health on samples of women who gave birth from April 1993 to December 2002. In using the PRAMS data, we assumed that the data were accurately weighted to estimate the number of unintended pregnancies at the statewide level. In applying statewide rates of births from unintended pregnancies, CSO data were adjusted only for income distribution (using Medicaid status as a proxy for income). The adjustment assumes that women with similar Medicaid status (non-Medicaid, medical-only citizens, grant recipients and medical-only non-citizens) have the same rates of unintended pregnancies in every CSO throughout the state. Because income is not the only factor that contributes to the variability in unintended pregnancies, the actual differences among CSOs are probably much greater than the differences based on these estimates.

CSO-level abortion statistics were based on county-level abortion data. This assumes that the women in a CSO have the same rates of abortion as the county as a whole. For CSOs that wholly comprise a county and have a homogenous population this assumption is quite reasonable; however, differences may exist between the county-level abortion rates and the actual CSO-level abortion rates in counties with a diverse and wide-spread population.

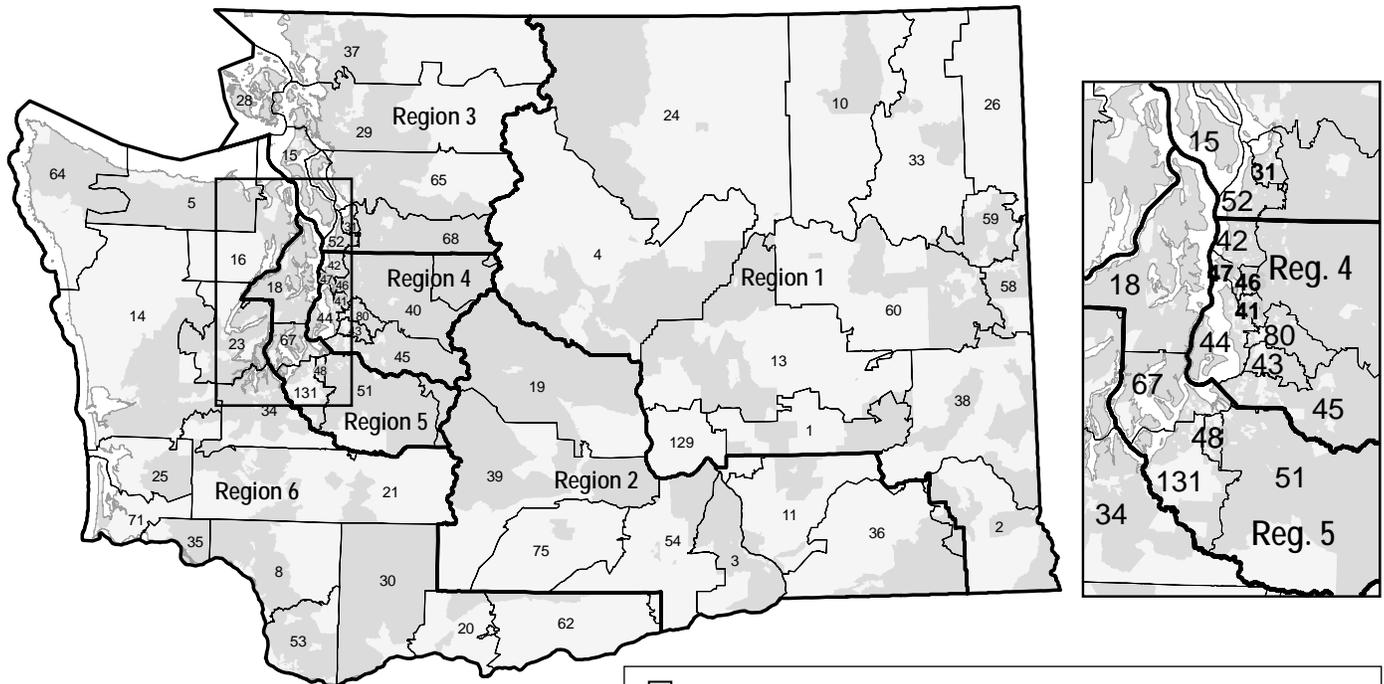

In *Pregnancy and Induced Abortion Statistics 2002*, DOH-CHS reported that the abortions for 1995 had been underreported. Adjusted county abortion rates were estimated using straight-line interpolation techniques. The DOH-CHS did not adjust the actual numbers at an age-specific

level. As a result, the age-specific abortion rates in this report, which are based on unadjusted age-specific numbers, may underestimate the actual rates in some counties.

The National Center for Health Statistics (NCHS) uses the term *birth rate* somewhat differently than that used in this report. The NCHS defines the *crude birth rate* as total live births divided by the total population (times 1000). NCHS also defines the *fertility rate* as the total live births divided by the total population of women 15-44 years old (times 1000). This report calculates age-specific birth rates as the number of live births in each age group divided by the number of women in the same age group (times 1000).

Abortion Rate, women ages 15-44	11.9	10.6	9.7	11.3	9.8	17.7	19.6
Women ages 15 - 24	24.6	16.8	20.6	25.4	21.0	30.4	32.8
Women ages 25 - 44	7.5	8.3	5.5	5.4	4.9	11.9	13.5

* Rates per 1,000 women in the given age category.

*** Rates or % not calculated when number of events were less than 5.

Rates and numbers for unintended pregnancy and abortions are synthetic estimates. For details, see Methods and Technical Appendices.

Low-income women: lived in mostly low-income areas, defined as having at least 27% of the population at or below 185% of the FPL.

Higher-income women: lived in mostly higher-income areas, defined as having less than 27% of the population at or below 185% of the FPL.

APPENDIX C

Technical Methods

Adjusting Unintended Pregnancy Rates by Medicaid Status

Unintended pregnancy statistics help states assess the need for family planning services (Dietz et al., 1999; Melvin et al., 2000). They also help states, counties and communities evaluate the health of mothers and their babies and address issues related to health care access (DOH, 2002).

Unintended pregnancy statistics were calculated based on PRAMS data collected by the Washington State Department of Health under the auspices of the Centers for Disease Control and Prevention. One question in the annual PRAMS survey of women who gave birth asks how the woman felt about her pregnancy at the time of conception. Women who answered that at the time of conception they would have preferred to become pregnant at a later time or not at all are categorized as having a birth from an unintended pregnancy.

Due to the PRAMS sampling strategy and sample size, it is not possible to directly compute numbers of unintended pregnancies at either the county or CSO level. As with counties, some CSOs were not sampled at all and even the more populated CSO areas have too few women to calculate reliable estimates of births from unintended pregnancies.

Because PRAMS data do not allow for reliable CSO-level unintended pregnancy estimates, synthetic estimation techniques were used in this report. To create CSO-level estimates that reflected the diversity of women giving birth across Washington CSOs, the statewide unintended pregnancy rates were adjusted by Medicaid status as a proxy for socioeconomic status. A similar method was used in *County Profiles Birth and Unintended Pregnancy Statistics* (April 2004) published by the Department of Social and Health Services.

Number of Births from Unintended Pregnancies: PRAMS sample data were linked to the First Steps Database, which contains Medicaid information, and weighted to produce an estimate of the statewide unintended pregnancy rate for women 15-44 years of age across four different Medicaid categories: Non-Medicaid, TANF/AFDC (grant recipients), medical-only citizens and medical-only non-citizens. These rates were then applied to the distribution of births to women in these four categories in each CSO to obtain each CSO's estimated number of unintended pregnancies.

Women that receive services based on programs that do not fall into any of the four categories above, or have unknown eligibility, were not included in the calculation of unintended pregnancies. This is a very heterogeneous group. Few of these women were included in the PRAMS sample and their rates of unintended pregnancy fluctuated drastically. The PRAMS sample sizes at the state level for these women ranged from 30 in 1999 to 69 in 1998 and the rate of unintended pregnancies ranged from 28.9% in 1993 to 93.9% in 1999.

In 2001-2002 an estimated 26.8% of births to higher-income women (non-Medicaid) were from unintended pregnancies, compared to 57.8% for medical-only citizens, 66.2% for grant recipients and 38.4% for medical-only non-citizens. We applied these ratios to the number of births in each of the four categories statewide. This methodology was used at the state level in order to allow for direct comparisons between the state-level estimates of unintended pregnancy statistics and CSO-level estimates. See the most recent County Profiles report (April 2004) for a more in-depth analysis of this synthetic estimation technique.

The following hypothetical example illustrates application of this weighting methodology: In 2001-2002, CSO X had 400 births distributed equally among the four Medicaid groups (non-Medicaid, grant recipients, medical-only citizens and medical-only non-citizens). The number of unintended births is estimated to be $(100 \times .268) + (100 \times .578) + (100 \times .662) + (100 \times .384) = 189$. CSO Y, a comparatively affluent CSO, also had 400 births: 275 to higher income women (non-Medicaid), 70 to Medicaid citizens, 30 to grant recipients and 25 to Medicaid non-citizens. The number of unintended births for CSO Y is estimated to be $144 = [(275 \times .268) + (70 \times .578) + (30 \times .662) + (25 \times .384)]$. CSO X's estimated unintended pregnancy rate would be 47% $[(189/400) \times 100]$, higher than CSO Y's estimated unintended pregnancy rate of 36% $[(144/400) \times 100]$ and higher than the state average of 40%.

The 1991-92 estimated number and percent of births from unintended pregnancies was calculated based on data from 1993-94, the first years PRAMS data were collected.

Percent of Births from Unintended Pregnancies is the proportion of births to women 15-44 that were unintended at the time of conception.

Estimating Abortion Statistics for CSOs

Abortion is defined by DOH as “the termination (spontaneous or induced) of a pregnancy before the fetus has attained viability.” All statistics in the DOH report refer to induced abortions.

The following hypothetical example illustrates application of this weighting methodology: CSO A has 2000 women aged 15-24 and 50% of the total births in CSO A occurred in County X and 50% occurred in County Y. County X has an abortion rate of 28 per 1000 women 15-24 and County Y has an abortion rate of 36 per 1000 women 15-24 years of age. The number of abortions for CSO A is

$$\frac{(.50 \times 2000)(28)}{1000} + \frac{(.50 \times 2000)(36)}{1000} = 64$$

The abortion rate for women 15-24 years of age in CSO A is 32 $[(64/2000) \times 1000]$.

Estimated numbers and rates of abortions were not published when the number of events was less than five.

The number of abortions at the regional level is the sum of the estimated number of abortions for the CSOs within that region.
